#### 1 Measurement

## 1.1 Instrument Uncertainty

All instruments have uncertainties:

- 1. Analogue Instruments: Half the smallest measurement unit
- 2. Digital Instruments: The smallest significant figure
- 3. Human reaction time:  $\pm 0.10$ s

## 1.2 Significant Figures

- 1. Adding or subtracting: Follow term with least decimal place
- 2. Multiplying or Dividing: Follow term with least significant figure

## 1.3 Propagation of error

For any  $f(a, \cdots)$  the general formula for  $\Delta f$  is:

$$\Delta f = \sqrt{\left(\frac{\partial f}{\partial a} \Delta a\right)^2 + \cdots}$$

Some specific examples:

1. 
$$f = a \pm b$$

$$\Delta f = \sqrt{(\Delta a)^2 + (\Delta b)^2}$$

2. 
$$f = ab$$
 or  $f = \frac{a}{b}$ 

$$\frac{\Delta f}{f} = \sqrt{\left(\frac{\Delta a}{a}\right)^2 + \left(\frac{\Delta b}{b}\right)^2}$$

#### 2 Mechanics

#### 2.1 Statics

When all objects are motionless (or have constant velocity),

$$\sum \mathbf{F}_{net} = 0$$
$$\sum \mathbf{\tau}_{net} = 0$$

Four basic forces to consider:

**Tension** Pulling force felt by a rope, string, etc. Every piece of rope feels a pulling force in both directions.

**Friction** Parallel to surface of contact, can be static or kinetic.

**Normal** Perpendicular to surface of contact, prevents object from falling through surface.

**Gravity** Force acting between two objects with mass. Always acts downwards for objects on surface of earth.

#### 2.2 Kinematics

$$egin{aligned} oldsymbol{v} &= \lim_{\Delta t o 0} rac{\Delta oldsymbol{x}}{\Delta t} = rac{doldsymbol{x}}{dt} = oldsymbol{\dot{x}} \ oldsymbol{a} &= rac{doldsymbol{v}}{dt} = rac{d^2oldsymbol{x}}{dt^2} = oldsymbol{\dot{x}} = oldsymbol{\ddot{x}} \end{aligned}$$

### 2.2.1 Polar Coordinates

Differentiation of unit vectors:

$$\dot{\hat{m{r}}}=\dot{ heta}\hat{m{ heta}} \ \dot{\hat{m{ heta}}}=-\dot{ heta}\hat{m{ heta}}$$

Velocity and acceleration in polar form:

$$egin{aligned} oldsymbol{r} &= r \hat{oldsymbol{r}} \ oldsymbol{v} &= \dot{oldsymbol{r}} = \dot{r} \hat{oldsymbol{r}} + r \dot{oldsymbol{ heta}} \hat{oldsymbol{ heta}} \ oldsymbol{a} &= \dot{oldsymbol{v}} = (\ddot{r} - \dot{oldsymbol{ heta}}^2 r) \hat{oldsymbol{r}} + (r \ddot{oldsymbol{ heta}} + 2 \dot{r} \dot{oldsymbol{ heta}}) \hat{oldsymbol{ heta}} \end{aligned}$$

## 2.3 Dynamics

$$m{F} = mm{\ddot{x}}$$
  $m{F}_{action} = -m{F}_{reaction}$ 

Free body diagram techniques:

- 1.  $\Sigma \mathbf{F}_{net} = 0$  for massless pulleys
- 2. Conservation of string

Solving differential equations in 1-dimension:

1. 
$$F = f(t)$$

$$m \int_{v_0}^{v(t)} dv' = \int_{t_0}^{t} f(t')dt'$$
$$m \int_{x_0}^{x(t)} dx' = \int_{t_0}^{t} v(t')dt'$$

2. 
$$F = f(x)$$

$$a = \frac{dv}{dt} = \frac{dv}{dt} \frac{dx}{dx} = v \frac{dv}{dx}$$

$$m \int_{0}^{v(x)} v' dv' = \int_{0}^{x} f(x') dx'$$

3. 
$$F = f(v)$$

$$m \int_{v_0}^{v(t)} \frac{dv'}{f(v')} = \int_{t_0}^t dt'$$

#### 2.3.1 Friction

Kinetic and static friction:

$$egin{aligned} oldsymbol{f_k} &= \mu_k oldsymbol{N} \ oldsymbol{f_s} &< \mu_s oldsymbol{N} \end{aligned}$$

Static friction does no work.

#### 2.3.2 Constraining Forces

For any rigid body, there are 6 degrees of freedom (DF). There can be constraining forces (C) acting on the body.

- Statics: C + DF = 6
- Dynamics  $C + DF \ge 6$

There are 3 assumptions made for a body moving without any constraint:

- 1.  $f_{ij} \parallel r_{ij}$
- 2.  $r_{ij}$  is constant for any 2 points in a rigid body
- 3.  $\mathbf{f}_{12} + \mathbf{f}_{21} = 0$

#### 2.3.3 Fictitious Forces

For any vector  $\boldsymbol{A}$  in a moving frame, we calculate its time derivative in a frame rotating at  $\omega$  respect to the stationary frame:

$$\frac{d\mathbf{A}}{dt}_{\text{stat}} = \frac{d\mathbf{A}}{dt}_{\text{mov}} + \boldsymbol{\omega} \times \mathbf{A}$$

Let r be the position vector of the object in an accelerated frame and R be the vector to the origin of the accelerated frame, then the possible forces that acts on r in the moving frame are:

$$\frac{d^2 \mathbf{r}}{dt^2} = \frac{\mathbf{F}}{m} - \frac{d^2 \mathbf{R}}{dt^2} - \boldsymbol{\omega} \times (\boldsymbol{\omega} \times \mathbf{r})$$
$$-2\boldsymbol{\omega} \times \boldsymbol{v} - \frac{d\boldsymbol{\omega}}{dt} \boldsymbol{r}$$

- 1. Translational force:  $-m\frac{d^2\mathbf{R}}{dt^2}$
- 2. Centrifugal force:  $-m\omega \times (\omega \times r)$ 3. Coriolis force:  $-2m\omega \times v$
- 4. Azimuthal force:  $-m\frac{d\omega}{dt}\mathbf{r}$

## 2.4 Conservation Laws

Energy  $W_{NC} = 0$ 

Momentum  $\Sigma \mathbf{F}_{net} = 0$ 

Angular Momentum  $\Sigma \tau_{net} = 0$ 

#### 2.5 Energy

For a force in one dimension:

$$\begin{split} m\dot{\boldsymbol{r}}\frac{d\dot{\boldsymbol{r}}}{d\boldsymbol{r}} &= \boldsymbol{F}(\boldsymbol{r})\\ \frac{1}{2}m|\dot{\boldsymbol{r}}|^2 &= E + \int_{\boldsymbol{r}_0}^{\boldsymbol{r}}\boldsymbol{F}(\boldsymbol{r}')\cdot d\boldsymbol{r}' \end{split}$$

We can then define potential energy:

$$U(\boldsymbol{r}) = -\int_{\boldsymbol{r_0}}^{\boldsymbol{r}} F(\boldsymbol{r}') \cdot d\boldsymbol{r}'$$

Work-Energy theorem:

$$W_{AB} = \int_{r_1}^{r_2} F(r') \cdot dr'$$
  
 $W_{\text{total}} = \Delta KE$ 

Conservative forces are forces that only depend on *position*. For conservative forces:

$$\oint \mathbf{F} \cdot d\mathbf{r} = 0$$

$$\nabla \times \mathbf{F} = 0$$

$$\mathbf{F} = -\nabla U$$

$$W_C = -\Delta U$$

For non-conservative forces:

$$W_{NC} = \Delta(K+U) = \Delta E$$

Where E is defined as the mechanical energy of the system.

#### 2.5.1 Power

Power is the rate of work done per unit time:

$$P = \frac{dW}{dt}$$

Mechanical power:

$$P = \frac{d}{dt} \oint \mathbf{F} \cdot d\mathbf{r} = \frac{d}{dt} \oint \mathbf{F} \cdot \frac{d\mathbf{r}}{dt} dt$$
$$= \mathbf{F} \cdot \mathbf{v}$$

#### 2.6 Momentum

Momentum is defined as:

$$p = mv$$

When there is no net force on the system,

$$\sum \mathbf{F}_{net} = 0 \Rightarrow \frac{d\mathbf{p}}{dt} = 0$$
$$\Rightarrow \mathbf{p} \text{ is conserved}$$

Impulse is defined as:

$$\mathcal{I} = \int_{t_1}^{t_2} \mathbf{F}(t)dt = \int_{t_1}^{t_2} \frac{d\mathbf{p}}{dt}dt$$
$$\mathcal{I} = \mathbf{p}(t_2) - \mathbf{p}(t_1) = \Delta \mathbf{p}$$

For perfectly elastic collisions of two objects in 1-D, relative velocity is constant.

$$v_1 - v_2 = -(v_1' - v_2')$$

For other collisions in 1-D, we have the coefficient of restitution e:

$$e = -\frac{v_2' - v_1'}{v_2 - v_1} \qquad 0 \le e \le 1$$

## 2.7 Lagrangian Mechanics

The Lagrangian method is based on the *principle of stationary action*.

$$\mathcal{L}(\dot{x}, x, t) = T - V$$
$$\frac{d}{dt} \left( \frac{\partial \mathcal{L}}{\partial \dot{x}} \right) - \frac{\partial \mathcal{L}}{\partial x} = 0$$

## 2.8 Hamiltonian Mechanics

The Hamiltonian  $\mathcal{H}$  can be used for the conservation of energy:

$$\mathcal{H}(\dot{x}, x, t) = T + V$$
$$\dot{\mathcal{H}} = 0$$

Where T is the kinetic energy, and V is the potential energy of the system.

#### 2.9 Central Forces

For any particle subjected to a central force,

$$F(r) = m\ddot{r} - mr\dot{\theta}^2$$
$$L = mr^2\dot{\theta}$$

Because angular momentum L is constant, we can look at central forces systems in 1-dimension.

$$V_{\text{eff}}(r) = \frac{L^2}{2mr^2} + V(r)$$
$$E = V_{\text{eff}} + \frac{1}{2}m\dot{r}^2$$

#### 2.9.1 Gravity

For any two point masses of  $m_1$  and  $m_2$  in empty space, the gravitational force between them is:

$$oldsymbol{F} = rac{Gm_1m_2}{|oldsymbol{r}|^2}oldsymbol{\hat{r}}$$

Where r is the position vector of one mass respect to the other, and G is the gravitational constant.

$$F = mg$$

For a mass m at the Earth's surface, where  $g=9.81m/s^2$  pointing downwards.

## 2.10 Uniform Circular Motion

For a point mass moving in uniform circular motion, we define:

$$\omega = \frac{v}{r}$$

The centripetal acceleration a and the force required to keep the object in its circular path:

$$a = \frac{v^2}{r} = \omega^2 r$$
$$F = \frac{mv^2}{r} = m\omega^2 r$$

# 2.11 Rotational Dynamics (Constant $\hat{L}$ )

## 2.11.1 Angular Momentum

The angular momentum of a point mass is defined as:

$$oldsymbol{L} = oldsymbol{r} imes oldsymbol{p}$$

For a flat object lying on a 2-D plane rotating with angular speed  $\omega$ :

$$m{L} = \int m{r} imes m{p} = \int r^2 \omega m{\hat{z}} dm$$

If we define the moment of intertia about the z-axis to be  $I_z = \int (x^2 + y^2) dm$ , we have:

$$L_z = I_z \omega$$

$$T = \int \frac{1}{2} m \mathbf{v}^2 = \int \frac{r^2 \omega^2}{2} dm$$

$$= \frac{1}{2} I_z \omega^2$$

For the z-component of  $\boldsymbol{L}$  and kinetic energy T.

#### 2.11.2 General Motion

For an object with a moving center of mass, and rotating at  $\omega$  about it,

$$L = r_{\text{CM}} \times p_{\text{CM}} + I_{\text{CM}} \omega \hat{z}$$
$$T = \frac{1}{2} m v_{\text{CM}}^2 + \frac{1}{2} I_{\text{CM}} \omega^2$$

## **2.11.3** Torque

Torque is defined as:

$$au = m{r} imes m{F}$$

Using an origin satisfying any of the following conditions to calculate L,

- 1. The origin is the center of mass
- 2. The origin is not accelerating
- 3.  $(\mathbf{R} \mathbf{r_0})$  is parallel to  $\mathbf{r_0}$ , the position of the origin in a fixed coordinate system

$$\frac{d\mathbf{L}}{dt} = \sum \boldsymbol{\tau}_{\mathrm{ext}}$$

When there is no external torque, we have the conservation of angular momentum.

$$\tau_{\rm ext} = I\alpha$$

Where  $\alpha = \frac{d\omega}{dt}$  is the angular acceleration.

#### 2.11.4 Angular Impulse

Angular impulse is defined as:

$$\mathcal{I}_{ heta} = \int_{t_1}^{t_2} oldsymbol{ au}(t) dt = \Delta oldsymbol{L}$$

If we have a force F(t) applied at a constant distance R from the origin,

$$oldsymbol{ au}(t) = oldsymbol{R} imes oldsymbol{F}(t) \ \mathcal{I}_{ heta} = oldsymbol{R} imes \mathcal{I} \ \Delta oldsymbol{L} = oldsymbol{R} imes (\Delta oldsymbol{p})$$

#### 2.11.5 Parallel-axis Theorem

Let an object of mass M rotate about its center of mass with the same frequency  $\omega$  as the center of mass rotates about the origin (with radius R):

$$L_z = (MR^2 + I_{\rm CM})\omega$$

Thus if the moment of inertia of an object is  $I_0$  about a particular axis, its moment of inertia about a parallel axis separated by R is:

$$I = MR^2 + I_0$$

## 2.11.6 Perpendicular-axis Theorem

For flat 2-D objects in the x-y plane, and orthogonal axes x, y and z:

$$I_z = I_x + I_y$$

## 2.11.7 Moments of Inertia

Center of mass for an object of mass M:

$$R_{\mathrm{CM}} = rac{\int r dm}{M}$$

Common moments of inertia (taken about center of mass unless stated):

- 1. Point mass at r from axis:  $mr^2$
- 2. Rod of length L about center:  $\frac{1}{13}mL^2$
- 3. Rod of length L about one end:  $\frac{1}{3}mL^2$
- 4. Solid disk of radius r perpendicular to axis:  $\frac{1}{2}mr^2$
- 5. Hollow sphere with radius r:  $\frac{2}{3}mr^2$
- 6. Solid sphere with radius r:  $\frac{2}{5}mr^2$

## 2.12 General Rotational Motion

For any body moving in space, its motion can be written as a sum of its translational motion and a rotation about an axis at a particular time.

## 2.12.1 Angular Velocity

The angular velocity vector  $\boldsymbol{\omega}$  points along the axis of rotation, with a magnitude equal to its angular speed. Its direction is determined by convention of the right hand rule. For an object rotating at  $\boldsymbol{\omega}$ , the velocity of a point at  $\boldsymbol{r}$  is:

$$oldsymbol{v} = oldsymbol{\omega} imes oldsymbol{r}$$

Angular velocities add like vectors. Let  $S_1$ ,  $S_2$  and  $S_3$  be coordinate systems. If  $S_1$  rotates with  $\omega_{1,2}$  with respect to  $S_2$ , and  $S_2$  rotates with  $\omega_{2,3}$  with respect to  $S_3$ , then  $S_1$  rotates instantaneously with respect to  $S_3$  at:

$$\boldsymbol{\omega}_{1,3} = \boldsymbol{\omega}_{1,2} + \boldsymbol{\omega}_{2,3}$$

## Perpendicular-axis The- 2.12.2 Angular Momentum

$$L = \int r \times (\boldsymbol{\omega} \times r) dm$$
$$= \mathbf{I} \boldsymbol{\omega}$$

I is the moment of inertia tensor:

$$\begin{pmatrix} \int (y^2 + z^2) & -\int xy & -\int zx \\ -\int xy & \int (z^2 + x^2) & -\int yz \\ -\int zx & -\int yz & \int (x^2 + y^2) \end{pmatrix}$$

The kinetic energy of the object is given by:

$$\begin{split} T &= \int \frac{1}{2} ||\boldsymbol{\omega} \times \boldsymbol{r}||^2 dm \\ &= \frac{1}{2} \boldsymbol{\omega} \cdot \mathbf{I} \boldsymbol{\omega} = \frac{1}{2} \boldsymbol{\omega} \cdot \boldsymbol{L} \end{split}$$

To find the angular momentum for an object of mass M in general motion, let the position of its center of mass be R, its velocity be V. Then:

$$\boldsymbol{L} = M(\boldsymbol{R} \times \boldsymbol{V}) + \boldsymbol{L}_{\mathrm{CM}}$$

The kinetic energy of the object is:

$$T = \frac{1}{2}MV^2 + \frac{1}{2}\boldsymbol{\omega}'\boldsymbol{L}_{\mathrm{CM}}$$

Where  $\omega'$  and  $L_{\rm CM}$  are measured about the center of mass along axes parallel to the fixed-frame axes.

## 2.12.3 Principal Axes

A principal axis is an axis of rotation  $\hat{\omega}$  such that  $\mathbf{I}\hat{\omega} = I\hat{\omega}$ . An object can rotate about a principal axis at constant angular velocity with no external torque. An orthonormal set of principle axis exists for every object.

## 3 Special Relativity

#### 3.1 Postulates

- 1. The speed of light has the same value in all inertial frames
- 2. Physical laws remain the same in all inertial frames

#### 3.2 Kinematics

#### 3.2.1 Lorentz Transform

$$x = \gamma(x' + \beta ct')$$

$$y = y'$$

$$z = z'$$

$$ct = \gamma(\beta x' + ct')$$

Where 
$$\gamma = \frac{1}{\sqrt{1 - \frac{v^2}{c^2}}}$$
 and  $\beta = \frac{v}{c}$ .

#### 3.2.2 Fundamental Effects

## Length contraction

$$l' = \frac{l}{\gamma}$$

Where l is the proper length.

#### Time dilation

$$t' = \gamma t$$

Where t is the proper time.

## Loss of simultaneity

$$\Delta t = \frac{Lv}{c^2}$$

Two events separated by L and  $\Delta t$  in the rest frame will appear simultaneous to an observer moving at v.

## Longitudinal velocity addition

$$v_x' = \frac{u+v}{1+uv/c^2}$$

Where u is the velocity of an object in the frame traveling at v respect to the lab frame, and  $v'_x$  is the xvelocity of the object viewed by the lab frame.

## Transverse velocity addition

$$v_y' = \frac{u_y}{\gamma_v(1 + u_x v/c^2)}$$

Where  $u_y$  and  $u_x$  are velocity components of an object in the frame traveling at v respect to the lab frame, and  $v_y'$  is the y-velocity of the object viewed by the lab frame.

#### Longitudinal Doppler effect

$$f' = f\sqrt{\frac{1+\beta}{1-\beta}}$$

Where f' is the frequency observed of a moving source emitting at frequency f in its rest frame.

## 3.2.3 Minkowski Diagrams

Space-time diagrams with x and ct axes. Some properties are:

- 1. Light travels at  $45^{\circ}$  to horizontal.
- 2. x' and ct' axes of another moving frame are  $\theta$  to the x and ct axes respectively, with

$$tan(\theta) = \beta$$

3. Units on axes of the moving and stationary frames are related by:

$$\frac{x'}{x} = \frac{ct'}{ct} = \sqrt{\frac{1+\beta^2}{1-\beta^2}}$$

## 3.3 Dynamics

## 3.3.1 Momentum

$$oldsymbol{p} = \gamma_v m oldsymbol{v} = rac{m oldsymbol{v}}{\sqrt{1 - rac{v^2}{c^2}}}$$

#### 3.3.2 Energy

$$E^2 = p^2 c^2 + m^2 c^4$$

For massive particles:

$$E = \gamma mc^2 = \frac{mc^2}{\sqrt{1 - \frac{v^2}{c^2}}}$$

For massless particles(such as photons):

$$E = pc = \frac{hc}{\lambda}$$

#### 3.4 4-vectors

A 4-vector  $\vec{A} = (A_1, A_2, A_3, A_4)$  is a quantity that transforms as follows:

$$A'_1 = \gamma(A_1 + i\beta A_4)$$

$$A'_2 = A_2$$

$$A'_3 = A_3$$

$$A'_4 = \gamma(A_4 - i\beta A_1)$$

The dot product of two 4-vectors is invariant under Lorentz transformations:

$$\vec{A} \cdot \vec{B} = \vec{A'} \cdot \vec{B'}$$

#### 3.4.1 Different 4-vectors

**4-position** (dx, dy, dz, icdt)

4-vectors originate from the invariant interval ds.

$$\vec{ds}^2 = (dx, dy, dz, icdt)^2$$
  
=  $dx^2 + dy^2 + dz^2 - c^2 dt^2$ 

4-velocity  $\gamma_v(\boldsymbol{v},ic)$ 

To obtain other 4-vectors, we can multiply invariant quantities to the 4position vector, such as proper time:

$$d\tau = \frac{dt}{\gamma}$$

$$\vec{v} = \frac{ds}{d\tau}$$

$$= \gamma_v \left(\frac{dx}{dt}, \frac{dy}{dt}, \frac{dz}{dt}, ic\right)$$

$$= \gamma_v(\mathbf{v}, ic)$$

4-momentum  $(\boldsymbol{p}, i\frac{E}{c})$ 

As mass is invariant,

$$\vec{p} = m\vec{v}$$

$$= (\gamma_v m v, i\gamma_v m c)$$

$$= \left(p, i\frac{E}{c}\right)$$

For photons in x-direction, the 4-momentum vector is:

$$\vec{p} = \left(\frac{h}{\lambda}, 0, 0, i\frac{h}{\lambda}\right)$$

**4-wave**  $(k, i\frac{\omega}{c})$ 

For electromagnetic waves,

$$k = \frac{2\pi}{\lambda} = \frac{\omega}{c}$$

$$p = \frac{h}{\lambda} = \hbar k$$

$$E = hf = \hbar \omega$$

$$\vec{p} = \hbar \left( k, i \frac{\omega}{c} \right)$$

$$\vec{k} = \frac{\vec{p}}{\hbar}$$

**4-force**  $\gamma_v\left(\boldsymbol{f}, \frac{i}{c} \frac{dE}{dt}\right)$ 

$$ec{F} = rac{dec{p}}{d au} \ = \gamma_v \left( oldsymbol{f}, rac{d}{dt} \left( i rac{E}{c} 
ight) 
ight)$$

## 4 Electricity and Magnetism

## 4.1 Electrostatics

Coulomb's law The force between a point charge q and test charge Q:

$$\boldsymbol{F} = \frac{Qq}{\mathrm{r}^2} \mathbf{\hat{r}}$$

Where  $\mathbf{r} = \mathbf{r} - \mathbf{r'}$  is the displacement vector from Q at  $\mathbf{r}$  and q at  $\mathbf{r'}$ .

Superposition principle The interaction between any two charges is unaffected by any other charges

#### 4.1.1 Electric Field

The electric field of a point charge is defined as:

$$\boldsymbol{E} = \frac{\boldsymbol{F}}{Q} = \frac{q}{\mathrm{r}^2} \hat{\mathbf{r}}$$

For a continuous volume charge distribution  $\rho(\mathbf{r'})$ , we can use the superposition principle to get:

$$\boldsymbol{E}(\boldsymbol{r}) = \int_{\mathcal{V}} \frac{\rho(\boldsymbol{r'})}{\mathrm{r}^2} \hat{\mathbf{r}} d au'$$

Taking the divergence of  $\boldsymbol{E}$ , we get Gauss' law:

$$\nabla \cdot \mathbf{E} = 4\pi \rho(\mathbf{r})$$

$$\oint_{S} \mathbf{E} \cdot d\mathbf{a} = 4\pi Q_{\text{enc}}$$

Taking the curl of E:

$$\nabla \times \mathbf{E} = 0$$

$$\oint \mathbf{E} \cdot d\mathbf{l} = 0$$

For any surface charge in an electric field E, the field felt by an area element on the surface is:

$$m{E}_{ ext{felt}} = rac{1}{2} \left( m{E}_{ ext{above}} + m{E}_{ ext{below}} 
ight)$$

## 4.1.2 Electric Potential

As the line integral of the electrostatic field is path independent, we can define the potential at a point r:

$$V(r) = -\int_{\mathcal{O}}^{r} \mathbf{E} \cdot d\mathbf{l}$$

Where  $\mathcal{O}$  is a standard reference point, usually set to infinity. The potential

of a point charge can then be found, and with the superposition principle we can find the potential of any charge distribution:

$$V = \frac{q}{r}$$

$$V(r) = \int_{\mathcal{V}} \frac{\rho(r')}{r} d\tau'$$

Taking the gradient of the potential:

$$\boldsymbol{E} = -\nabla V$$
$$\nabla^2 V = -4\pi\rho$$

## 4.1.3 Work and Energy

The work needed to bring a charge Q from infinity to a point a is:

$$W = \int_{\infty}^{a} \mathbf{F} \cdot d\mathbf{l}$$
$$= -Q \int_{\infty}^{a} \mathbf{E} \cdot d\mathbf{l}$$
$$= QV(\mathbf{a})$$

The energy in a continuous charge distribution is:

$$W = \frac{1}{2} \int \rho V d\tau$$
$$= \frac{1}{8\pi} \int E^2 d\tau$$

Where the integral is taken over all space.

#### 4.1.4 Conductors

A perfect conductor has an unlimited supply of free charges.

- 1. E = 0 and  $\rho = 0$  inside a conductor
- 2. Any conductor is an equipotential
- 3. Just outside a conductor, E is perpendicular to the surface.

If we charge up two conductors with +Q and -Q, the potential between them is proportional to the charge Q (because the electric field is proportional to Q), and we define the constant of proportionality capacitance:

$$C = \frac{Q}{V}$$

The work done by charging a capacitor is:

$$W = \int_0^Q \frac{q}{C} dq = \frac{Q^2}{2C}$$
$$= \frac{1}{2}CV^2$$

#### 4.1.5 Image Charges

In certain special cases, a charge placed next to a grounded conductor has equivalents.

- 1. A point charge and a conducting sheet: An opposite charge in the mirror image position.
- 2. A point charge and a conducting sphere, or an infinite line charge and conducting cylinder: Opposite image charge and charge forms the Apollonius sphere/cylinder.

## 4.1.6 Uniqueness Theorems

First uniqueness theorem The solution to Laplace's equation  $(\nabla^2 V = 0)$  in some volume  $\mathcal{V}$  is uniquely determined if V is specified on the boundary surface  $\mathcal{S}$ .

Second uniqueness theorem In a volume  $\mathcal{V}$  surrounded by conductors and containing a specified charge density  $\rho$ , the electric field is uniquely determined if the total charge on each conductor is given.

## 4.2 Magnetostatics

#### 4.2.1 Lorentz Force Law

The force felt by:

1. A point charge q moving at velocity v through a magnetic field B:

$$\boldsymbol{F} = \frac{q}{c} \boldsymbol{v} \times \boldsymbol{B}$$

2. A line current I:

$$\mathbf{F} = \frac{I}{c} \int (d\mathbf{l} \times \mathbf{B})$$

3. A general volume current J per unit area perpendicular to flow:

$$\boldsymbol{F} = \frac{1}{c} \int (\boldsymbol{J} \times \boldsymbol{B}) d\tau$$

#### 4.2.2 Biot-Savart Law

The magnetic field created by a steady line current:

$$\boldsymbol{B}(\boldsymbol{r}) = \frac{I}{c} \int \frac{d\boldsymbol{l} \times \hat{\boldsymbol{r}}}{r^2}$$

## 4.2.3 Magnetic Fields

The magnetic field is divergence-free:

$$\nabla \cdot \boldsymbol{B} = 0$$

$$\oint \boldsymbol{B} \cdot d\boldsymbol{a} = 0$$

Taking the curl of the magnetic field gives Ampere's Law:

$$\mathbf{\nabla} \times \mathbf{B} = \frac{4\pi}{c} \mathbf{J}$$

$$\oint \mathbf{B} \cdot d\mathbf{l} = \frac{4\pi}{c} I_{\text{enc}}$$

## 4.3 Electrodynamics

## 4.3.1 Electromotive Force

For an electric field applied in a material:

$$oldsymbol{J} = rac{oldsymbol{E}}{
ho}$$

Where  $\rho$  is the resistivity constant depending on the material. This leads to Ohm's law:

$$V = IR$$
$$R = \rho \frac{l}{A}$$

The power delivered:

$$P = VI = I^2R$$

The electromotive force (emf)  $\mathcal{E}$  is the line integral of the force per unit charge driving the current:

$$\mathcal{E} = \oint \mathbf{E} \cdot d\mathbf{l}$$

 $\mathcal{E} = V$  for an ideal source.

#### 4.3.2 Faraday's Law

Faraday's law states that a changing magnetic flux  $\Phi$  induces an electric field:

$$\mathcal{E} = \oint \mathbf{E} \cdot d\mathbf{l} = -\frac{1}{c} \frac{d\Phi}{dt}$$
$$\mathbf{\nabla} \times \mathbf{E} = -\frac{1}{c} \frac{d\mathbf{B}}{dt}$$

#### 4.3.3 Inductance

If we have two current loops 1 and 2, the flux  $\Phi_2$  through loop 2 is proportional to the current through loop 1:

$$\Phi_2 = M_{21}I_1$$

Where  $M_{21} = M_{12}$  is the mutual inductance between these two loops. We can also define an self inductance L, for a single loop:

$$\Phi = LI$$

$$\mathcal{E} = -L\frac{dI}{dt}$$

#### 4.4 Electric Circuits

#### 5 Oscillations and Waves

Many questions involve solving linear differential equations. For such equations, linear combinations of solutions will also be a solution.

#### 5.1 Oscillations

## 5.1.1 Simple Harmonic Motion

We have a spring force, F = -kx.

$$\ddot{x} + \omega^2 x = 0$$
, where  $\omega = \sqrt{\frac{k}{m}}$   
 $x(t) = A\cos(\omega t + \phi)$ 

#### 5.1.2 Damped Oscillators

In addition to the spring force, we now have a drag force  $F_f = -bv$ , and the total force  $F = -kx - b\dot{x}$ .

$$\ddot{x} + 2\gamma \dot{x} + \omega^2 x = 0$$

Where  $2\gamma = b/m$  and  $\omega^2 = k/m$ . Let  $\Omega = \sqrt{\gamma^2 - \omega^2}$ .

$$x(t) = e^{-\gamma t} (Ae^{\Omega t} + Be^{-\Omega t})$$

## Underdamping $(\Omega^2 < 0)$

$$x(t) = e^{-\gamma t} (Ae^{i\tilde{\omega}t} + Be^{-i\tilde{\omega}t})$$
$$= e^{-\gamma t} C\cos(\tilde{\omega}t + \phi)$$

Where  $\tilde{\omega} = \sqrt{\omega^2 - \gamma^2}$ . The system will oscillate with its amplitude decreasing over time. The frequency of oscillations will be smaller than in the undamped case.

## Overdamping $(\Omega^2 > 0)$

$$x(t) = Ae^{-(\gamma - \Omega)t} + Be^{-(\gamma + \Omega)t}$$

The system will not oscillate, and the motion will go to zero for large t.

## Critical damping $(\Omega^2 = 0)$

We have  $\gamma = \omega$ , and:

$$\ddot{x} + 2\gamma \dot{x} + \gamma^2 x = 0$$

In this special case,  $x = te^{-\gamma t}$  is also a solution:

$$x(t) = e^{-\gamma t} (A + Bt)$$

Systems with critical damping go to zero the quickest.

#### 5.1.3 Driven Oscillators

We have to solve differential equations of this form:

$$\ddot{x} + 2\gamma \dot{x} + ax = \sum_{n=1}^{N} C_n e^{i\omega_n t}$$

We first find particular solutions for each n, by guessing solutions of the form  $x_{p_n}(t) = Ae^{i\omega_n t}$ :

$$-A\omega_n^2 + 2iA\gamma\omega_n + Aa = C_n$$
$$x_{p_n}(t) = \frac{C_n}{-\omega_n^2 + 2i\gamma\omega_n + a}e^{i\omega_n t}$$

Using the superposition principle, the final solution is a linear combination of the general solution and the particular solutions, with the combination constants determined by initial conditions.

## 5.1.4 Coupled Oscillators

Normal modes are states of a system where all parts are moving with the same frequency. General strategy to find normal modes:

- 1. Write down the n equations of motions corresponding to the n degrees of freedom the system has.
- 2. Substitute  $x_i = A_i e^{i\omega t}$  into the differential equations to get a system of linear equations in  $A_i$ , with  $i = 1, 2, \dots, n$
- 3. Non-trivial solutions exist if and only if the determinant of the matrix is zero. Solve for  $\omega$ , and subsequently find  $A_i$

The motion of the system can then be decomposed into linear combinations of its normal modes.

8

#### 5.1.5 Small Oscillations

For an object at a local minimum of a potential well, we can expand V(x) about the equilibrium point:

$$V(x) = V(x_0) + V'(x_0)(x - x_0) + \frac{1}{2!}V''(x_0)(x - x_0)^2 + \cdots$$

As  $V(x_0)$  is an additive constant, and  $V'(x_0) = 0$  by definition of equilibrium,

$$V(x) \approx \frac{1}{2}V''(x_0)(x - x_0)^2$$
$$F = -\frac{dV}{dx} = -V''(x_0)(x - x_0)$$
$$\omega = \sqrt{\frac{V''(x_0)}{m}}$$

## 5.2 Wave Equation

A wave is a disturbance of a continuous medium that propagates with a fixed shape at constant velocity. In one dimension:

$$u(z,t) = u(z - vt, 0) = f(z - vt)$$

All such functions f are the solutions to the wave equation:

$$\frac{\partial^2 u}{\partial x^2} = \frac{1}{v^2} \frac{\partial^2 u}{\partial t^2}$$

Where v is the speed of propagation.

## 5.2.1 String with Fixed Ends

If the equation is subject to the following initial and boundary conditions:

$$u_x(0,t) = u_x(L,t) = 0$$
  

$$u(x,0) = f(x)$$
  

$$u_t(x,0) = g(x)$$

The solution for these conditions is:

$$u(x,t) = \sum_{n=1}^{\infty} \sin \frac{n\pi}{L} x \cdot \left( a_n \sin \frac{n\pi\alpha}{L} t + b_n \cos \frac{n\pi\alpha}{L} t \right)$$
$$a_n = \frac{2}{n\pi\alpha} \int_0^L g(x) \sin \frac{n\pi x}{L} dx$$
$$b_n = \frac{2}{L} \int_0^L f(x) \sin \frac{n\pi x}{L} dx$$

#### 5.2.2 D'Alembert's Solution

For an infinite string, it can be proved that any solution to the wave equation can be written as a superposition of two waves of velocity v, one travelling to the left, the other travelling to the right. For the initial conditions:

$$u(x,0) = f(x)$$
$$u_t(x,0) = g(x)$$

The solution of the wave equation is:

$$u(x,t) = \frac{1}{2} \left[ f(x+vt) + f(x-vt) + \frac{1}{v} \int_{x-vt}^{x+vt} g(x') dx' \right]$$

## 5.2.3 Electromagnetic Waves

#### 6 Optics

## 6.1 Geometric Optics

Results from Fermat's principle of least time:

$$\theta_{\text{incidence}} = \theta_{\text{reflection}}$$
 $n_1 \sin \theta_1 = n_2 \sin \theta_2$ 

Sign convention:

- Light rays travel from left to right
- f is positive if surface makes rays more convergent
- Distances are measured from the surface (left is negative)
- $s_o$  is negative for real objects
- $s_i$  is positive for real images
- y above optical axis is positive

$$\frac{1}{f} = \frac{1}{s_i} + \frac{1}{s_o}$$
$$M = \frac{y_i}{y_o} = -\frac{s_i}{s_o}$$

For thin lenses and mirrors:

$$\frac{1}{f} = \frac{2}{R}$$

For composite thin lenses:

$$\frac{1}{f} = (n-1)\left(\frac{1}{R_1} + \frac{1}{R_2}\right)$$

Lens formed by interface of two materials with different n:

$$\frac{n_2 - n_1}{R} = \frac{n_2}{s_i} + \frac{n_1}{s_o}$$

#### 6.2 Polarization

For polarized light:

$$E = E_0 \cos \theta$$
$$I = I_0 \cos^2 \theta$$

For unpolarized light:

$$\langle I \rangle = I_0 \langle \cos^2 \theta \rangle = \frac{I_0}{2}$$

Brewster angle at which all reflected light at an interface is polarized:

$$\tan \theta_i = \frac{n_t}{n_i}$$

## 6.3 Physical Optics

Interference is the superposition of wave amplitudes when waves overlap.

#### 6.3.1 Double Slit:

Occurs when slits are of negligible width, distance between slits comparable to wavelength, such that diffraction effects are insignificant. For bright fringes:

$$d\sin\theta = m\lambda$$
$$y_m = R\frac{m\lambda}{d} \qquad m \in \mathbb{Z}$$

For incident medium's refractive index  $n_i$ , reflection medium's refractive index  $n_r$ , if  $n_i < n_r$ , the reflected wave undergoes a  $\frac{\pi}{2}$  phase shift.

#### 6.3.2 Single Slit:

Occurs when size of slit is comparable to wavelength. Location of dark fringes when wavelets at distance  $\frac{a}{2}$  destructively interfere:

$$\sin \theta = \frac{m\lambda}{d}$$

$$y_m = x \frac{m\lambda}{a} \qquad m \in \mathbb{Z}$$

## 6.3.3 Intensity in Diffraction Patterns

For double slit interference:

$$I = I_{\text{max}} \cos^2 \left( \frac{\pi d \sin \theta}{\lambda} \right)$$

For single slit diffraction:

$$I = I_{\text{max}} \left[ \frac{\sin(\pi a \sin \theta / \lambda)}{\pi a \sin \theta / \lambda} \right]^2$$

Double slit including effects of diffraction:

$$I = I_{\text{max}} \cos^2 \left( \frac{\pi d \sin \theta}{\lambda} \right)$$
$$\cdot \left[ \frac{\sin(\pi a \sin \theta / \lambda)}{\pi a \sin \theta / \lambda} \right]^2$$

## 7 Thermodynamics

If two objects are in thermal equilibrium with a third system, then they are in equilibrium with each other.

## 7.1 Thermal Expansion

For linear expansion, the change in length is:

$$\Delta L = \alpha L_0 \Delta T$$

Where  $\alpha$  is the coefficient of linear expansion. For area expansion, use approximately  $2\alpha$ . For volume expansion, use approximately  $3\alpha$ .

## 7.2 Kinetic Theory of Gases

#### 7.2.1 Ideal Gas Law

An ideal gas' molecules are treated as non-interacting point particles. For an ideal gas of N particles at pressure P, volume V and temperature T:

$$PV = NK_BT$$

For a non-ideal gas, the Van der Waals correction to the ideal gas law is:

$$\left(P + a\left(\frac{n}{V}\right)^2\right)(V - bn) = nRT$$

Where a and b are constants.

#### 7.2.2 Internal Energy

Different gases at the same temperature have the same average kinetic energy. Thus we define temperature of a substance to be its average kinetic energy. For a monatomic ideal gas:

$$\frac{1}{2}m\langle v^2\rangle = \frac{3}{2}kT$$

For a gas molecule with r atoms, its total kinetic energy, center of mass kinetic energy and internal vibrational/rotational energy are given by:

$$E_{\text{Total}} = \frac{3r}{2}kT$$
 
$$E_{\text{COM}} = \frac{3}{2}kT$$
 
$$E_{\text{Internal}} = \frac{3(r-1)}{2}kT$$

The equipartition theorem states that each degree of freedom a molecule has contributes an extra  $\frac{1}{2}KT$  of kinetic energy.

#### 7.2.3 Maxwell Distribution

For an ideal gas, the distribution of its velocities is:

$$f(v) = 4\pi v^2 \left(\frac{m}{2\pi kT}\right)^{\frac{3}{2}} e^{-\frac{mv^2}{2kT}}$$

From this distribution, we can get the average speed of a particle:

$$\langle v \rangle = \sqrt{\frac{8kT}{\pi m}}$$

The most probable velocty is the maximum point of the distribution:

$$v_{\rm mp} = \sqrt{\frac{2kT}{m}}$$

For any two particles, their average relative speed is:

$$\langle v_{\rm rel} \rangle = \sqrt{2} \langle v \rangle = \sqrt{\frac{16kT}{\pi m}}$$

From this, we can get the mean free path of a particle, the average distance a particle travels before hitting another particle:

$$l_m = \frac{1}{4\pi\sqrt{2}r^2n}$$

Where n is the number density of the particle and r is its radius.

#### 7.2.4 Diffusion

For a substance undergoing diffusion due to a concentration gradient  $\frac{dc}{dx}$ , the diffusive flux J is:

$$J = DA \frac{dc}{dx}$$

## 7.3 Heat Teansfer

For heat transfer through a material with length l, area A and thermal conductivity K between two heat reservoirs  $T_1 > T_2$ :

$$\frac{dQ}{dt} = \frac{KA(T_1 - T_2)}{l}$$

For a blackbody at temperature T radiating heat away:

$$\frac{dQ}{dt} = \sigma A T^4$$

The heat transferred by changing the temperature of a solid of mass m with heat capacity c is:

$$\Delta Q = mc\Delta T$$

## 7.4 Thermodynamic Processes

In all the process described below, the heat Q that goes into the gas is positive, and the work done on the gas W is positive. The first law of thermodynamics states that the change of internal energy U is:

$$U = Q + W$$
$$U(\gamma - 1) = NkT$$

Where  $\gamma = C_p/C_v$  is the ideal gas constant and  $C_v = C_p - k$ .

## 7.4.1 Isochoric

In this constant volume process:

$$W = 0$$

$$Q = NC_v \Delta T$$

$$U = Q$$

#### 7.4.2 Isobaric

In a constant pressure volume expansion from  $V_1$  to  $V_2$ :

$$W = P(V_1 - V_2)$$
$$Q = NC_p \Delta T$$
$$U = NC_v \Delta T$$

## 7.4.3 Isothermal

For an isothermal expansion from  $V_1$  to  $V_2$ :

$$W = NkT \ln \left(\frac{V_1}{V_2}\right)$$
$$Q = -W$$
$$U = 0$$

## 7.4.4 Adiabatic

For an adiabatic process,

$$W = -\int PdV$$

$$Q = 0$$

$$U = W$$

Integrating the work done, we get the following relation:

$$PV^{\gamma} = \text{constant}$$

#### 7.5 Heat Engines

The efficiency of a heat engine that takes in  $Q_H$  and gives out  $Q_L$  while doing work W, its efficiency is given by:

$$\eta = \frac{|W|}{|Q_H|}$$
$$= 1 - \frac{|Q_L|}{|Q_H|}$$

The efficiency of a heat pump that uses W to pump  $Q_L$  from the col reservoir is:

$$\eta = \frac{|Q_L|}{|W|}$$

All reversible engines operating between the same two temperatures have the same efficiency as a Carnot engine, as you can fit many infinitisimally small Carnot cycles into any reversible cycle:

$$\eta_{\text{carnot}} = 1 - \frac{T_L}{T_H}$$

## 7.6 Second Law of Thermodynamics

- A process whose only net result is to take heat from a reservoir and convert it to heat is impossible.
- No heat engine can working between two temperatures  $T_1$  and  $T_2$  can have a higher efficiency than a reversible engine.

## 7.7 Entropy

## 7.7.1 Macroscopic Definition

Entropy is the measure of disorder. If heat is added reversibly into a system at temperature T, the increase in entropy in the system is:

$$dS = \frac{dQ}{T}$$

Entropy is a state function that doesn't depend on the path travelled. The total entropy change in the system and surroundings for a reversible process is zero. For an irreversible process, the total entropy change is always positive. At  $T=0,\,S=0$ . This is the third law of thermodynamics.

## 7.7.2 Microscopic Definition

Boltzmann defined entropy of a system by counting the number of indistinguishable microstates w inside:

$$S = k \ln w$$

#### 8 Quantum Mechanics

## 8.1 Schrödinger's Equation

 $\Psi(x,t)$  is a complex wave function of time and position, the one-dimensional Schrödinger's equation is given by:

$$i\hbar\frac{\partial\Psi}{\partial t} = -\frac{\hbar^2}{2m}\frac{\partial^2\Psi}{\partial x^2} + V\Psi$$

If we denote the complex conjugate of the wave function to be  $\Psi^*$ , the conjugate of Schrödinger's equation is:

$$-i\hbar\frac{\partial\Psi^*}{\partial t} = \frac{\hbar^2}{2m}\frac{\partial^2\Psi^*}{\partial x^2} - V\Psi^*$$

At time t, the probability of finding a particle from x = a to x = b is:

$$\int_a^b |\Psi(x,t)|^2 dx = \int_a^b \Psi \Psi^* dx$$

#### 8.1.1 Normalization

All wave functions must be normalized, so that the probability of finding the particle over all space is 1:

$$\int_{-\infty}^{\infty} |\Psi(x,t)|^2 dx = 1$$

Once a function is normalized, it remains normalized as time evolves:

$$\frac{d}{dt} \int_{-\infty}^{\infty} \Psi \Psi^* = 0$$

#### 8.1.2 Expectation Values

An expectation value of an observed quantity is the average of the measurement performed on many "copies" of the system at the same time.

$$\begin{split} \langle x \rangle &= \int_{-\infty}^{\infty} x |\Psi(x,t)|^2 dx \\ &= \int_{-\infty}^{\infty} \Psi^* x \Psi dx \\ \langle p \rangle &= m \frac{d \langle x \rangle}{dt} \\ &= \int_{-\infty}^{\infty} \Psi^* \left( -i\hbar \frac{\partial}{\partial x} \right) \Psi dx \end{split}$$

In general, the expectation value of any quantity is:

$$\langle Q(x,p)\rangle = \int \Psi^* Q\left(x, -i\hbar \frac{\partial}{\partial x}\right) \Psi dx$$

## 8.2 Time Independent Solution

We solve Schrödinger's equation by separation of variables. Let:

$$\Psi(x,t) = \psi(x)\phi(t)$$

Then the equation can be written as:

$$\begin{split} i\hbar\psi\frac{\partial\phi}{\partial t} &= -\frac{\hbar^2}{2m}\frac{\partial^2\psi}{\partial x^2}\phi + V\phi\psi\\ \left(\frac{i\hbar}{\phi}\frac{\partial\phi}{\partial t}\right) + \left(\frac{\hbar^2}{2m\psi}\frac{\partial^2\psi}{\partial x^2} - V(x)\right) &= 0 \end{split}$$

As the two terms in the equation are independent of each other and they sum to zero, they must be constant. If we let:

$$E = \frac{i\hbar}{\phi} \frac{\partial \phi}{\partial t}$$
$$\phi(t) = e^{iE/\hbar t}$$

The time independent solution is given by:

$$-\frac{\hbar^2}{2m}\frac{\partial^2 \psi}{\partial x^2} + V(x)\psi = E\psi$$

If we define the Hamiltonian operator  $\hat{\mathbf{H}} = -\frac{\hbar^2}{2m} \frac{\partial^2}{\partial x^2} + V$ ,

$$\hat{H}\psi = E\psi$$
